

Fotodiode nanofir obtinute prin metoda sablon

Dr. Ionut Enculescu

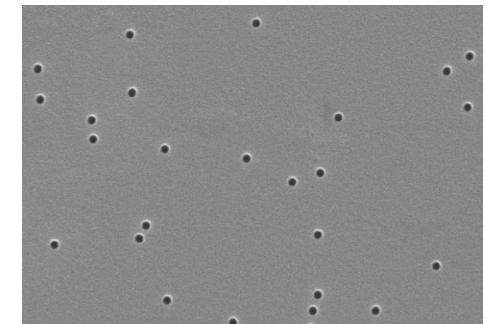

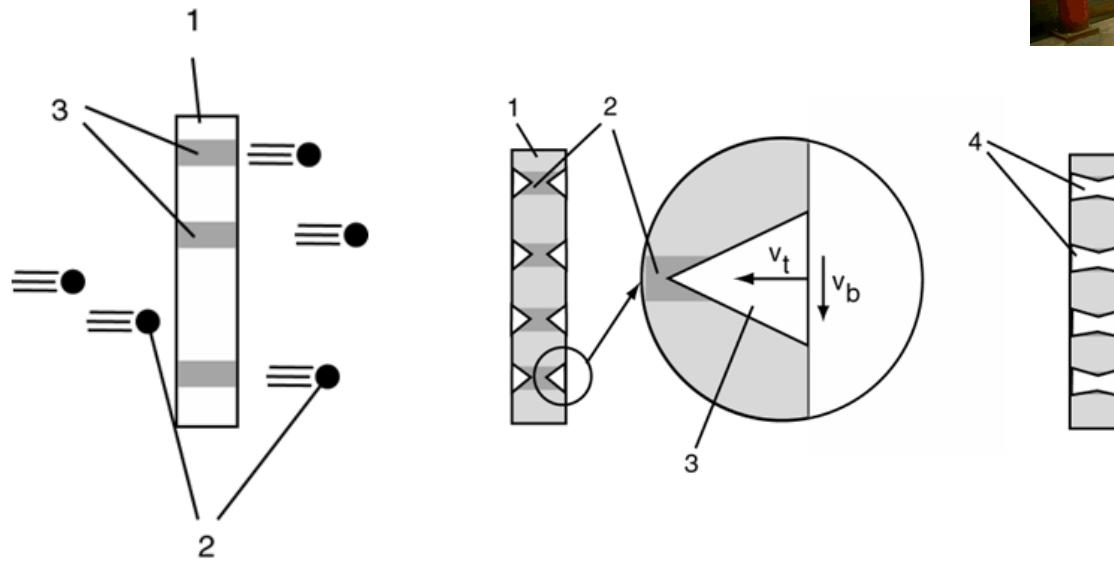

Metoda sablon permite obtinerea unor nanostructuri cu morfologie controlata

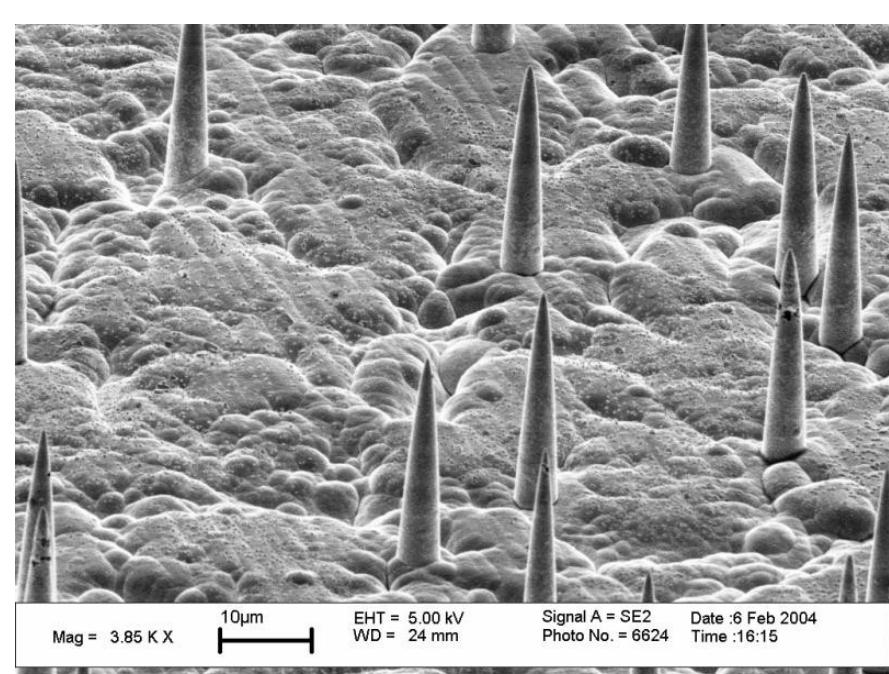

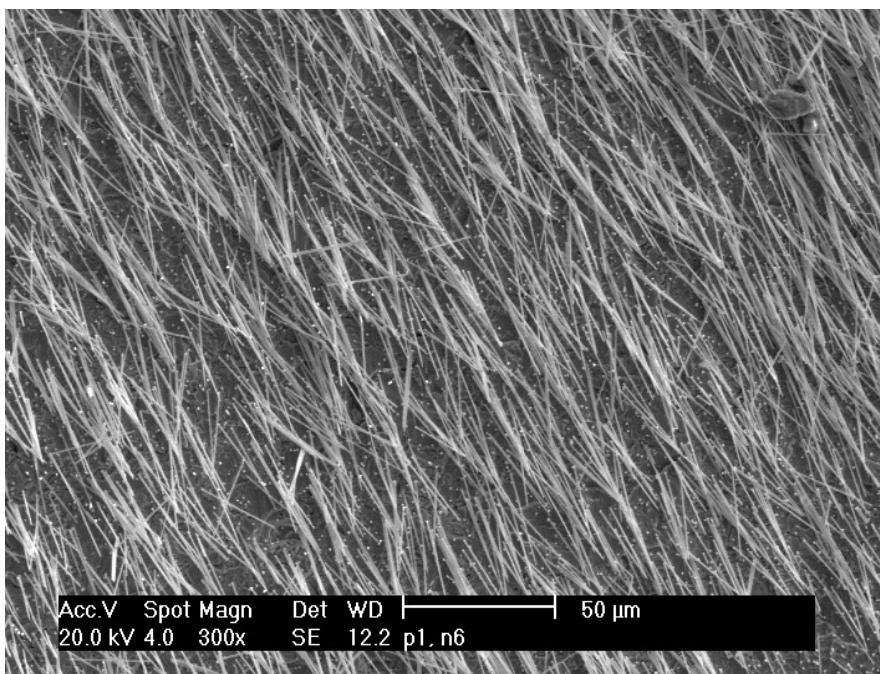

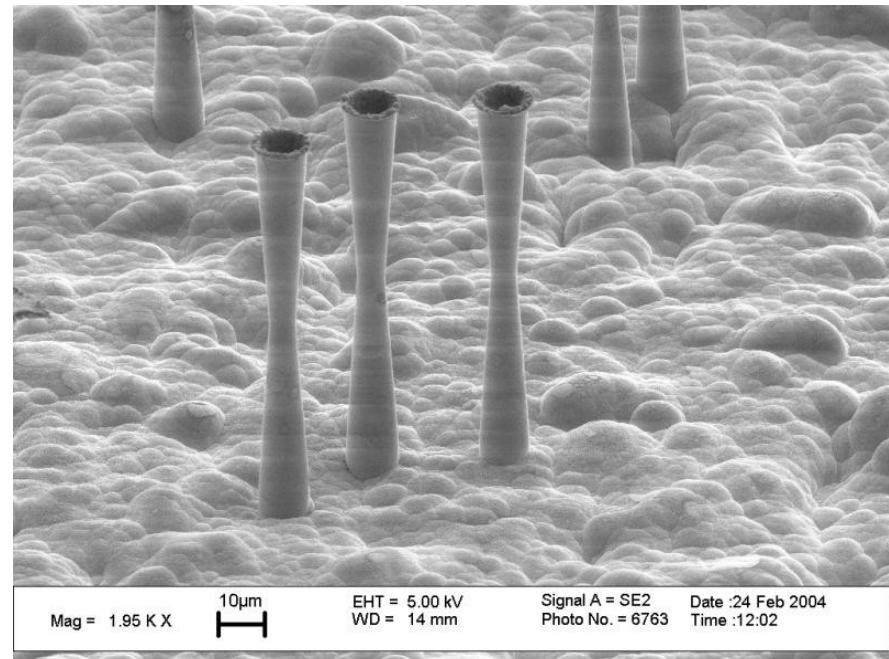

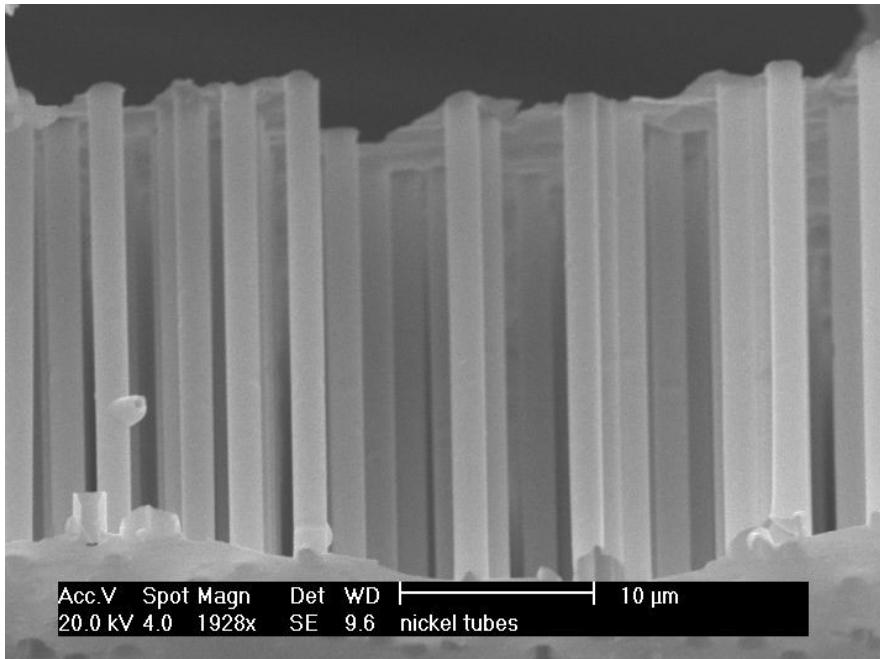

Ideea este de a obtine nanostructuri functionale intr-un mod simplu si reproductibil.

Metoda sablon in abordarea noastra:

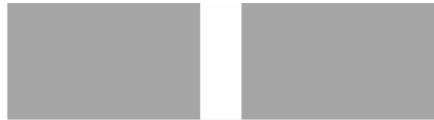

Iradierea unei folii de polimer cu ioni grei rapizi

Corodarea controlata a urmelor ionilor

Algoritmul de preparare a nanofirelor multisegment cu proprietati fotovoltaice:

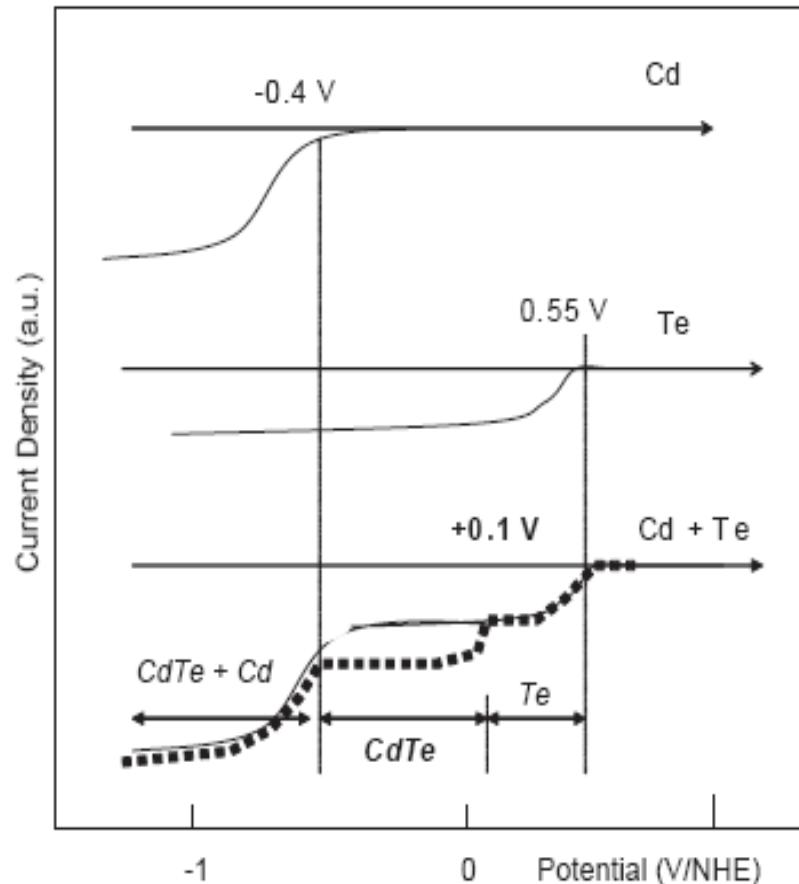

- 1** *1. membrana sablon continand nanopori;*
- 2** *2. Depunerea electrodului de lucru (strat metalic de aur sau platina obtinut prin sputtering sau evaporare in vid) si a primului segment metalic (electrochimic);*
- 3** *3. Depunerea segmentelor semiconductoare si umplerea completa a nanoporilor (incluzand cresterea unei structuri emisferice pe suprafata membranei pentru a obtine un contact electric stabil);*
- 4** *4. Depunerea celui de al doilea electrod (electrod transparent de ITO sau oxid de zinc) pentru a permite contactarea nanofirelor dar si iluminarea acestora. Depunerea va fi realizata folosind un fascicul de electroni pulsat, metoda ce permite obtinerea de straturi subtiri de calitate fara incalzirea substratelor.*

Depunerea electrochimica a CdTe

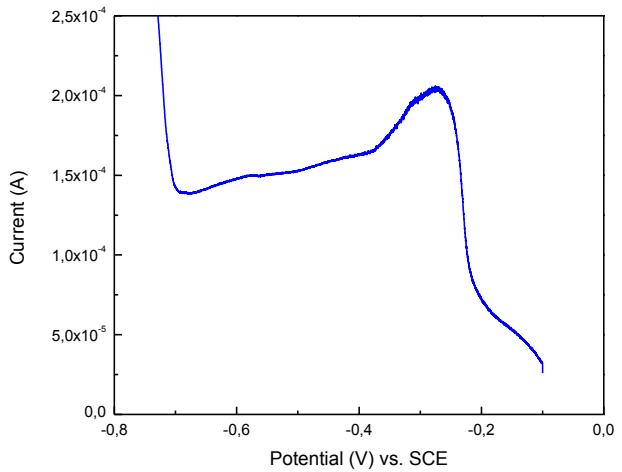

Depunerea CdTe din solutie apoasa:

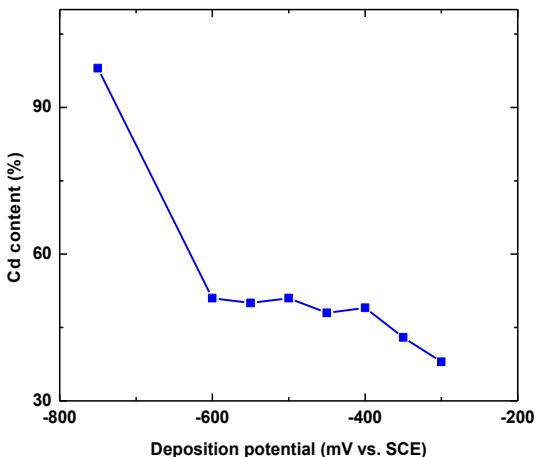

- a) depunerea Te;
- b) depunerea Cd;
- c) depunerea CdTe, linia continua corespunde depunerii fara nici o interactie intre Cd si Te elementale. Linia punctata corespunde situatiei in care se formeaza compusul CdTe tinand cont de energia libera de formare a compusului. Depunerea compusului stoichiometric se realizeaza intr-un domeniu larg de potential.

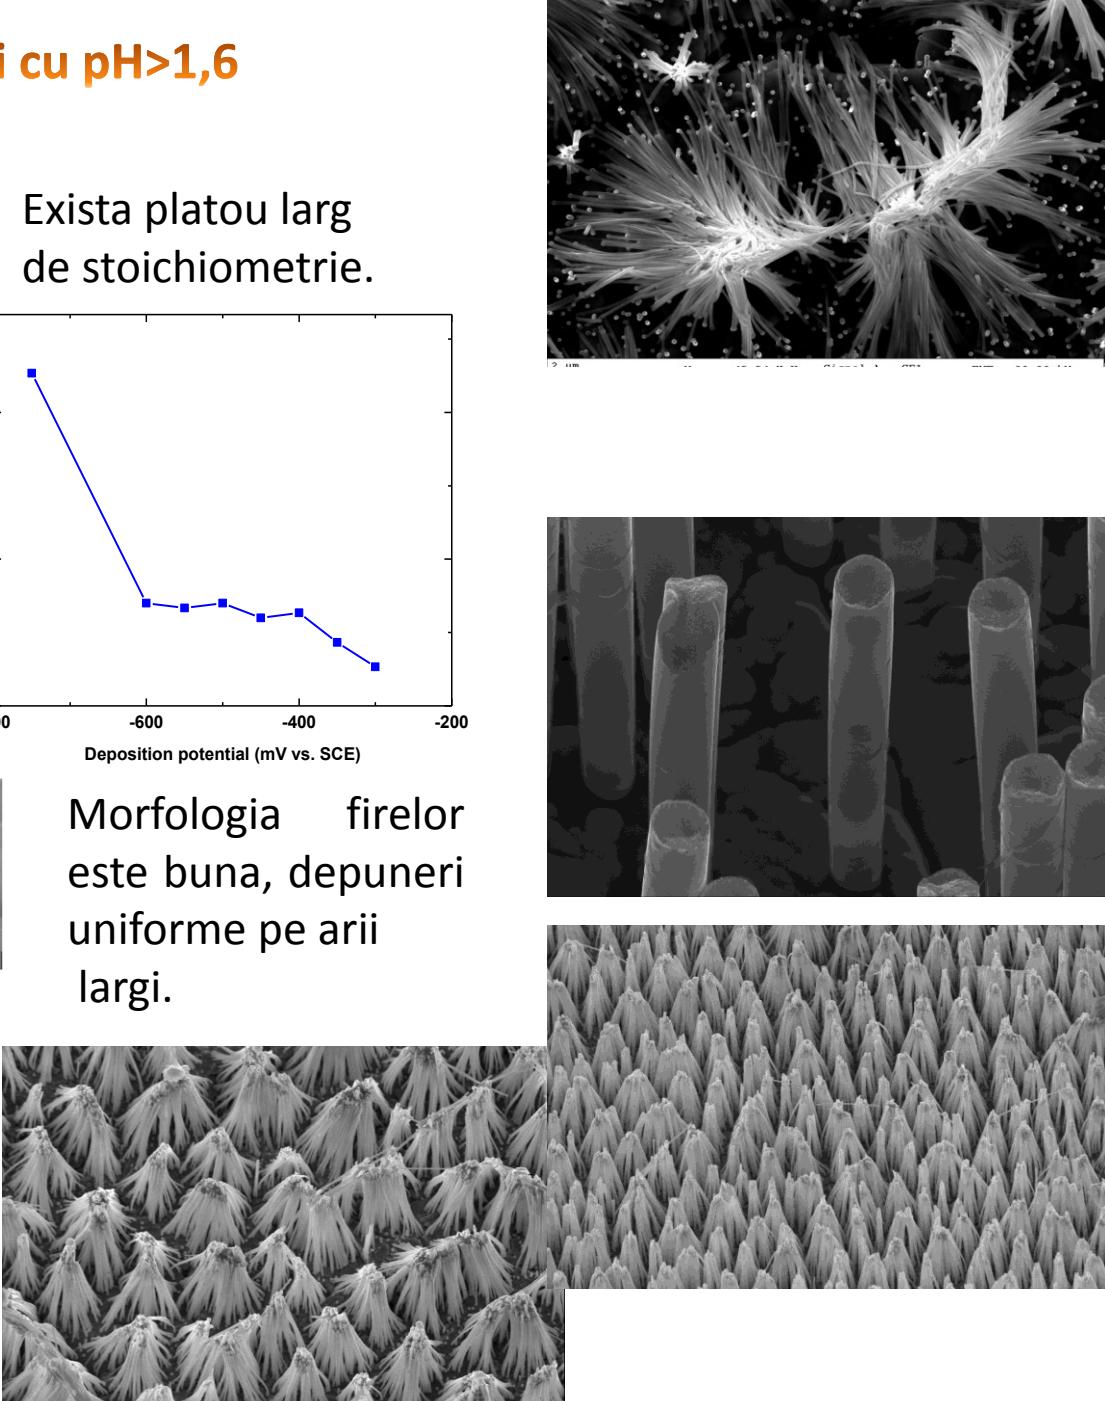

Baie continand PVP si cu pH>1,6

Exista platou larg de stoichiometrie.

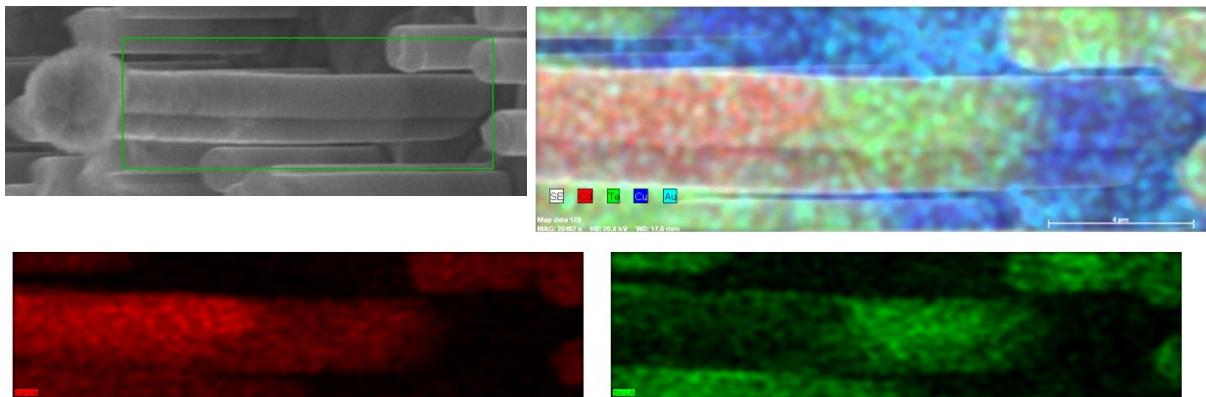

Morfologia firelor este buna, depuneri uniforme pe arii large.

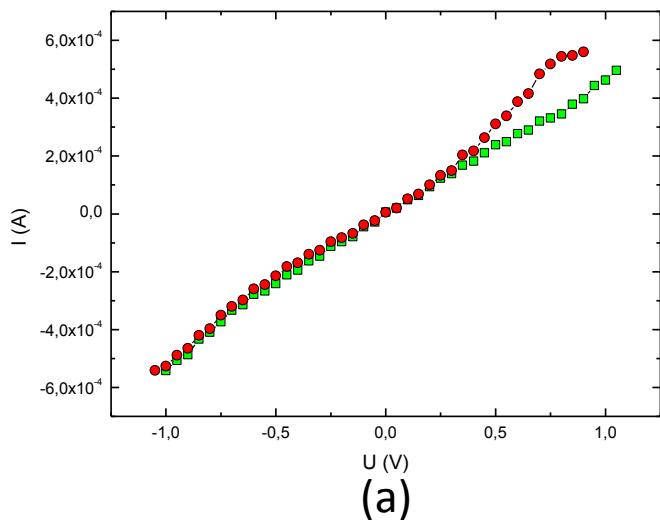

Fire policristaline cu structura cubica.

Depunerile de fire multisegment. Fotoconductor si fotodiode nanofir.

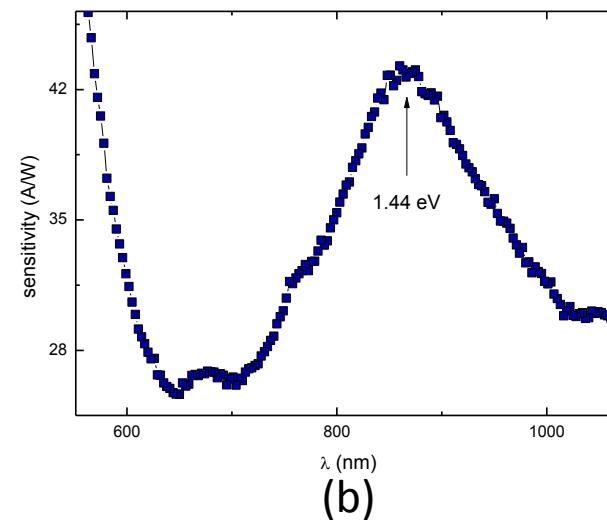

Depunerile la potențiale diferite duc la creșterea de segmente cu compozitii diferențiate.

Fire multisegment (imagini SEM si EDX mapping evidențiind segmentele de Cd și CdTe (fiecare culoare reprezintă un element: roșu pentru Cd, verde pentru Te, albastru este Cu, bleu Au)).

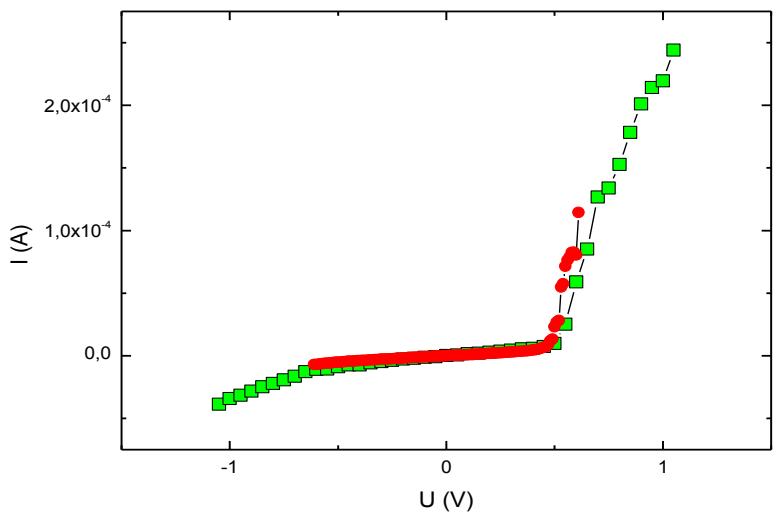

(a)

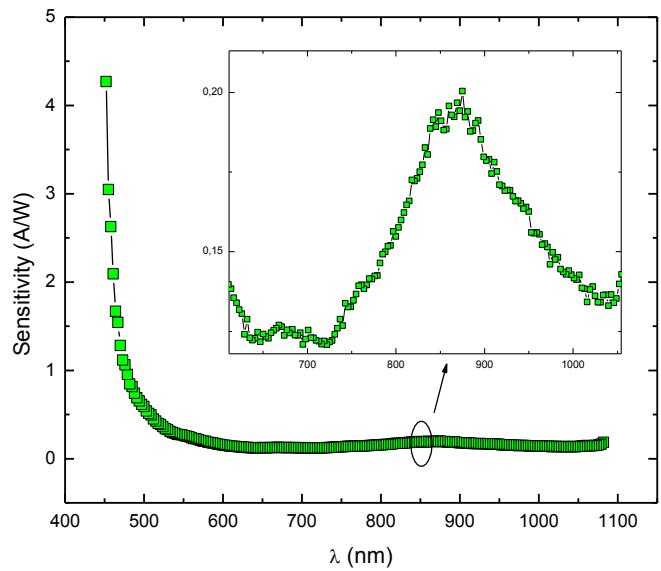

(b)

(a) Caracteristici I-V la temperatura camerei pentru matrice de fire multisegment Cd–CdTe–Cd: patrate pline reprezinta curentul la intuneric, cu cercuri goale este reprezentata caracteristica cand proba este iluminata. (b) Sensibilitatea spectrala a probei. Maximul corespunde valorii benzii interzise pentru CdTe. Baia de depunere: 0,2M Cd, 1mM Te si 0,1% PVP la pH 2,1.

Depuneri de fire multisegment. Fotoconductori si fotodiode nanofir.

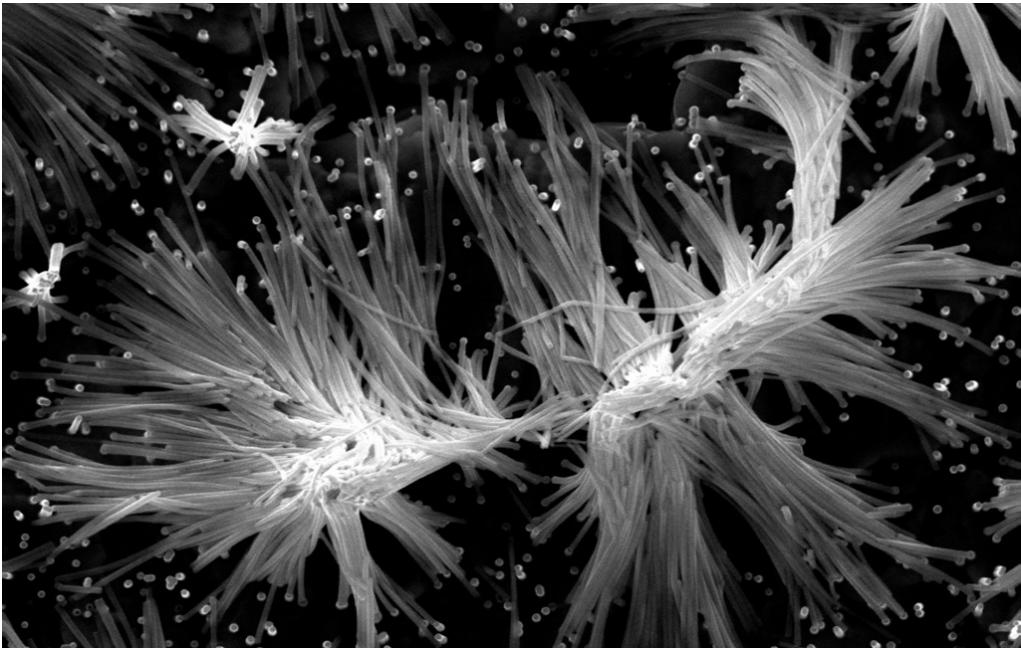

*Caracteristica I-V pentru o matrice de diode nanofir multisegment Cd-CdTe(p)-CdTe(n)-Cd:
verde - curentul la intuneric, rosu – curentul
cand proba este iluminata*

*Sensibilitatea spectrala a aceleasi
matrici de diode nanofir.*

Urmatorul pas va fi obtinerea unor diode nanofir heterojonctiune: CdTe – CdS si CdTe - ZnO

Imagine pe coperta revistei *Nanotechnology* 21(10), 2010.
